The fall occasion of Statistics Canada’s Fruit and Vegetable Survey gathers information regarding crops grown in the current year, including acreage, quantity sold and value received. For the fall 2009 survey, a section was added to collect revised data from the previous year. For 2010, a split sample was used to assess the impact of dependent interviewing (where the respondent is provided last year's response in the question) versus independent interviewing. This paper describes the motivation for the additional section along with the benefits and challenges associated with each interviewing method, and presents results from a series of evaluations.
